Q&A

End

- Describes a pedestrian population trend estimation method using location data of smartphone users.
- Intended to be an alternative to traffic censuses using tally counters.
- Using smartphone users' location data accumulated on Yahoo! Japan.
- Tackles the problem of data shortage when a target area is a small region by using a Gaussian kernel.

Q&A

End

- Knowing the number of pedestrians in a time or place can be an essential data source for market research.
- Traditional method: Traffic censuses using tally counters are still commonly used.
 - 1 Requires many survey crews and much time.
 - 2 Temporal and spatial limitation.
- Location-based services (LBSs) are widely used by smartphone users
- two problems remain
 - 1 How to pick out only pedestrians.
 - 2 How to set the research area and period.

- The location data are provided by smartphone users through services of Yahoo! Japan, contains:
 - Latitude
 - Longitude
 - Horizontal accuracy
 - Time stamp (at a second rate)
 - Anonymized user ID (changes after 24 hours)

Q&A

End

- Assumes that the number of records in an area is proportional to the people present in the area.
 - Determine target areas(polygonal) and target days
 - Number of records existing in the area hourly is counted and then multiplied by a proper factor.
 - The date has errors more than 300 meters are eliminated.

Q&A

End

- Non-pedestrian records
 - stationary users (e.g. in offices)
 - passing users (e.g. on trains)
- Time continuous estimation
- Sparsity with the smallness of target areas.

Eliminating non-pedestrian data

Q&A

End

- Data are extracted user-by-user(by user id).
- Approximate mean velocity is estimated an hour before or after a person visits the target area.
- The records where velocities both before and after are high or near zero are eliminated.
