Q&A

End

- Describes a pedestrian population trend estimation method using location data of smartphone users.
- Intended to be an alternative to traffic censuses using tally counters.
- Using smartphone users' location data accumulated on Yahoo! Japan.
- Tackles the problem of data shortage when a target area is a small region by using a Gaussian kernel.

Q&A

End

- Knowing the number of pedestrians in a time or place can be an essential data source for market research.
- Traditional method: Traffic censuses using tally counters are still commonly used.
  - 1 Requires many survey crews and much time.
  - 2 Temporal and spatial limitation.
- Location-based services (LBSs) are widely used by smartphone users
- two problems remain
  - 1 How to pick out only pedestrians.
  - 2 How to set the research area and period.

- Traffic censuses using tally counters were conducted for this research.
- The parameters to be determined are  $K$ , means how many pedestrians are represented by a single data point.

$$\hat{K}_p = \frac{M_p}{(\sum_{i=1}^n w_i)(\int_{t_1}^{t_2} f(t)dt)}$$

- $t_1$  and  $t_2$  are the census start and end times
- $M_p$  is total pedestrian number according to traffic census data of the day.
